1 **Executive Summary (Member #1)**

2 The Advisory Committee on Earthquake Hazards Reduction (ACEHR) finds that the
3 National Earthquake Hazards Reduction Program (NEHRP) has achieved significant
4 improvements, notably in its restructuring and broader collaborative efforts, since the
5 2004 reauthorization. NEHRP is committed to, and has made progress toward, becoming
6 a fully effective, collaborative, and focused program to secure the Nation against
7 unacceptable risks from seismic hazards. NIST, as the newly designated lead agency for
8 NEHRP, has formed a NEHRP office with a highly regarded NEHRP director. Each of
9 the other participating agencies—FEMA, NSF, and the USGS—has a significant role in
10 NEHRP, with the active participation of each agency’s director. The agency directors
11 serve on the newly expanded Interagency Coordinating Committee (ICC), which now
12 includes the Directors of the White House Office of Science and Technology Policy
13 (OSTP) and the Office of Management and Budget (OMB). NEHRP is responsible for
14 ensuring earthquake risk reduction opportunities to vulnerable communities, ranging
15 from conducting basic research to bridging research results to cost-effective mitigation.
16 The overall success of the NEHRP is highly dependent on legislative and administrative
17 support for increased funding.

18
19 To protect society against catastrophic earthquake-induced losses, NEHRP must become
20 a well recognized national priority. Risk reduction actions must be taken at the national,
21 state, and local levels. First and foremost, the state grant programs through FEMA must
22 be fully funded. Currently, there is a lack of financial support to state grant programs for
23 assisting communities, residents, and businesses in understanding their risk, sponsoring
24 pilot projects to illustrate cost-effective mitigation, and developing effective response
25 plans to facilitate the immediate and long-term recover process in the aftermath of a
26 severe earthquake. Earth science, engineering, and social science fundamental research is
27 critical to advancing our knowledge, and should be fully supported, but research findings
28 must be translated into practice. Without integrative research into the political, social, and
29 economic circumstances that motivate society to achieve community resilience,
30 implementation of proven earthquake resistant retrofit strategies will fall short. Sufficient
31 attention is not being paid to the development of national standards for lifelines and
32 existing buildings that will provide a resilient built environment. Strong motion recording
33 equipment must be installed rapidly through full funding of the Advanced National
34 Seismic System (ANSS) before the next major earthquake strikes. Through ANSS, the
35 USGS provides critical information to first responders after an earthquake and archival
36 data for engineers to evaluate the response of infrastructure systems, in addition to
37 ground shaking data to improve our understanding of the physics of earthquakes.

38
39 Key recommendations of the ACEHR are listed below by agency:

40
41 **FEMA**

- 42 • **Recommendation 1:** Revitalize state earthquake programs and support pilot
43 studies to characterize and mitigate unacceptable risk in communities.
- 44 • **Recommendation 2:** Fund FEMA at the authorized level. Assure funding is
45 dedicated to earthquake risk reduction.

- 1 • **Recommendation 3:** Continue to develop and maintain guideline documents that
2 will improve the effectiveness and reduce the cost of seismic protection for
3 lifelines, existing buildings, new buildings, and applied socioeconomic policies
4 for cost-effective mitigation. Promote their adoption and implementation to
5 stakeholders.

6

7 NIST

- 8 • **Recommendation 1:** NIST must secure the funding to effectively carry out its role
9 as the lead agency for NEHRP and its role in applied research and assistance in
10 implementation of cost-effective mitigation through codes and standards.
- 11 • **Recommendation 2:** NIST must plan for the development of multi-disciplinary
12 expertise within its own staff and foster relationships with other public agencies
13 and private-sector entities to accomplish the coordinated research to effectively
14 fulfill its obligations.

15

16 NSF

- 17 • **Recommendation 1:** NSF should enhance its support for multi-disciplinary
18 research related to NEHRP, which can be used as a model for reducing risks
19 associated with other natural and human-induced hazards. In particular, there is an
20 opportunity for the Engineering and Geosciences Directorates to partner with the
21 Social, Behavioral, and Economic Studies Directorate to understand the social and
22 economic factors that promote mitigation measures.
- 23 • **Recommendation 2:** NSF should enhance its support for curiosity-driven basic
24 research, which has been the foundation of many important technical discoveries.
25 Basic research sponsored by NSF educates the next generation of engineers and
26 scientists engaged in earthquake risk reduction. Such support is thus a means of
27 expanding the workforce in earthquake engineering and science.
- 28 • **Recommendation 3:** NSF should solicit support from other federal agencies to
29 leverage the NSF investments in NEES to address critical research needs for the
30 civil infrastructure. To date, research support for NEES has not matched the levels
31 needed by the earthquake community to reduce earthquake risks significantly.

32

33 USGS

- 34 • **Recommendation 1:** Fully fund ANSS at the level authorized in the current
35 NEHRP legislation. The USGS must make a commitment to work through the
36 Department of the Interior (DOI) and the OMB to ensure that this objective is
37 met.
- 38 • **Recommendation 2:** Proceed with multi-hazard demonstration projects, such as
39 the project being carried out in southern California that was initially funded by
40 Congress in Fiscal Year (FY) 2007. The demonstration projects should expand the
41 multi-hazard scope to include other high-risk areas as part of this effort.
- 42 • **Recommendation 3:** Enhance the coordination of internal and external research
43 activities in earthquake hazards uniformly throughout the United States, and
44 enhance the interaction of the USGS with its NEHRP partners in earthquake
45 engineering (NIST and NSF), earth science (NSF), and earthquake preparedness
46 (FEMA). The noteworthy level of coordination in some geographic areas, such as

1 California, and in some project areas, such as the National Seismic Hazard
2 Mapping project, should be extended to other geographic and project areas.
3

4 **Management, Coordination, and Implementation**

5

- 6 • Consistent with the change in the leadership of the NEHRP, ACEHR recommends
7 that USGS delegate post-earthquake investigation leadership to NIST, reconsider
8 the organization and deployment of reconnaissance teams, and sponsor
9 publication of discipline-oriented interactive media that archive collected data.

10
11 NEHRP began in 1977 with a healthy appropriation. Under the pressures of funding, this
12 appropriation has been depleted to well below the authorized levels and has not been
13 adjusted for inflation. In 2003, Congress reacted to the Nation's need and significantly
14 increased the authorization for NEHRP. Appropriations, however, are still far short of
15 what is needed for America's health and safety. Rather than strengthening NEHRP with
16 investments linked to authorized levels, the reverse has been the case for the past 5 years.
17 Unconscionably, NEHRP funding for FEMA's implementation programs to help
18 safeguard states and communities has been substantially reduced, resulting in serious
19 negative consequences with a dramatic increase in risk.
20

21 The United States invests more than \$1 trillion each year in new construction. It is now
22 well recognized that the condition of our infrastructure is in crisis, with more than \$2
23 trillion required over the coming decades to reconstruct what is needed to support a
24 vibrant country and economy. The Nation depends on its lifelines—power, surface
25 transportation, water, waste water, and communication—on a daily basis, and certainly
26 after a natural disaster. Failure of any of these lifelines following an earthquake can have
27 severe economic impacts on businesses and residents in the affected areas. Furthermore,
28 complex interrelationships of lifelines will produce many unforeseen and potentially
29 catastrophic consequences that will likely significantly increase damage and economic
30 losses. Consequently, the Nation is at high risk because there is no nationally sponsored
31 effort to direct the system-wide consideration of these resources and development of
32 appropriate design, construction, and renovation standards and programs. Moreover, a
33 small percentage of existing buildings will kill people in the next major earthquake.
34 These buildings need to be identified and mitigated. Since these actions require more than
35 engineering, we need to better understand the economic and political means to mitigate
36 high risk buildings that have great societal importance.
37

38 Studies have consistently shown that every dollar spent on NEHRP saves an average of 4
39 to 10 times that amount in avoided losses. ACEHR urgently recommends refocusing
40 NEHRP on achieving community resilience by fully funding implementation programs,
41 followed by those that are related to advancing our understanding and developing cost-
42 effective measures to achieve resilience against earthquakes.
43
44
45

1 **1. Introduction (Member #2)**

2 The NEHRP, first authorized in 1977, is embodied in Public Law 108–360. During the
3 most recent Program reauthorization in 2004, the ACEHR was created to oversee the
4 Program in four specific areas—new trends and developments, effectiveness, needed
5 revisions, and management. By statute, the ACEHR was formed of non-federal
6 employees representing research and academic institutions, industry standards
7 development organizations, state and local government, and financial communities across
8 all related scientific, architectural, and engineering disciplines. ACEHR is directed to
9 report within 1 year of formation, once every 2 years thereafter, and with due
10 consideration given to the recommendations of the USGS Scientific Earthquake Studies
11 Advisory Committee (SESAC). This is ACEHR’s first report. The Committee plans to
12 deliver a report annually hereafter.

13
14 ACEHR met in May and October 2007 and again in April 2008, for a total of 6 days of
15 hearings and deliberations. Multiple briefings were provided to the Committee by each of
16 the four NEHRP agencies relating to their current activities, the extent to which the
17 agencies are addressing their statutory requirements under the Program, the metrics being
18 used to monitor effectiveness, and planned changes. The Committee invited testimony
19 from four retired senior agency staff, one from each of the four agencies, to understand
20 some of the history and potential of the Program. Committee members developed white
21 papers related to new trends and developments in their areas of expertise that were
22 collated and discussed. The Committee received and reviewed the NEHRP annual reports
23 for 2007 and 2008 and was apprised of and consulted on the development of the 2008–
24 2012 NEHRP Strategic Plan. The meeting summaries adequately capture the information
25 provided to the Committee and the discussions that resulted in this first ACEHR report.

26
27 This report is a brief synthesis of the Committee’s observations, conclusions, and
28 recommendations related to the current status of NEHRP. It does not attempt to repeat
29 information received by ACEHR on the Program’s activities to date or Strategic Plans;
30 those topics are adequately addressed in NEHRP’s annual reports and Strategic Plans. It
31 also does not attempt to outline the process used to develop the recommendations, as that
32 is well noted in the meeting summaries, the trends and developments papers, and the
33 assessment scorecard used to gather opinions related to effectiveness.

34
35 The report is organized around the task areas assigned to ACEHR by its authorizing
36 legislation. Section 2, Program Effectiveness and Needs, is organized by NEHRP agency
37 and focuses on past and current accomplishments, future plans, and modifications needed
38 to address the goals of the 2008–2012 NEHRP Strategic Plan. Two or three prioritized
39 recommendations are included that relate to augmenting each agency’s activities beyond
40 their current efforts. Section 3, Management, Coordination, and Implementation of
41 NEHRP, includes complimentary assessments of the “new” NEHRP office within NIST,
42 of the effectiveness of the Program Coordination Working Group (PCWG), and of the
43 intrinsic value of the newly expanded ICC, which is composed of the Directors of the
44 NEHRP agencies and the Directors of the White House OSTP and the OMB. This report
45 also includes some suggestions on future ACEHR activities and membership and a single

1 recommendation related to post-earthquake investigations. The Appendix, Trends and
2 Developments in Science and Engineering, presents ACEHR's observations relating to
3 six disciplines that are highly relevant to NEHRP. These observations provide the
4 NEHRP agencies with an overview of the recent achievements that have been made and
5 the issues and challenges facing the industry, with suggestions on where future strategic
6 priorities should be focused.

7

8

1 **2. Program Effectiveness and Needs**

2
3 **2.1 Federal Emergency Management Agency (Member #1)**

4 ACEHR provides three recommendations for FEMA:

- 5
- 6 • **Recommendation 1:** Revitalize state earthquake programs and support pilot
 - 7 studies to characterize and mitigate unacceptable risks in communities.
 - 8 • **Recommendation 2:** Fund FEMA at the authorized level. Assure funding is
 - 9 dedicated to earthquake risk reduction.
 - 10 • **Recommendation 3:** Continue to develop and maintain guideline documents that
 - 11 will improve the effectiveness and reduce the cost of seismic protection for
 - 12 lifelines, existing buildings, new buildings, and applied socioeconomic policies
 - 13 for cost-effective mitigation. Promote their adoption and implementation to
 - 14 stakeholders.

15
16 FEMA is charged with the important mission of developing cost-effective measures to

17 reduce earthquake impacts on individuals, the built environment, and society-at-large,

18 and improving the earthquake resilience of communities nationwide. For FEMA to

19 succeed, the NEHRP agencies must bridge research findings to end users, including states

20 and communities.

21
22 ACEHR's most serious concern with FEMA is the steady erosion of its budget. The

23 funds allocated to FEMA for NEHRP in 2008 are roughly one-third the level of its 2002

24 NEHRP funding. The loss of this support has greatly reduced the capabilities of an

25 agency that has many significant accomplishments. Such past accomplishments include

26 developing and promoting HAZUS software; providing grants to states and communities,

27 including pilot studies; encouraging earthquake risk reduction for lifelines; providing

28 information on seismic design and mitigation, including the nurturing of industry

29 guidelines, standards, and codes for evaluating and mitigating existing buildings; and

30 transferring NEHRP recommendations into model building codes.

31
32 In previous years, FEMA had tremendous success working with states and communities,

33 providing guidance and support for risk-reduction implementation projects and policies.

34 This important work, however, has been seriously hampered in recent years by a lack of

35 prioritization, support, and funding from the Department of Homeland Security (DHS).

36 FEMA's effectiveness appears to be tied to DHS, and the Department has cut deeply into

37 the ability of FEMA to support NEHRP goals.

38
39 FEMA had a dedicated program until 2001 to provide assistance to states with high

40 earthquake risks by directly supporting their state earthquake program managers. Since

41 2003, that assistance has been subsumed into other DHS state and local homeland

42 security grant programs. The net effect has been to degrade the overall preparedness of

43 most state earthquake programs, as well as the visibility and effectiveness of their

44 managers. Few of these managers can identify or gain access to the resources they

45 previously received. It is vital to increase the overall level of FEMA NEHRP support

46 within DHS to help revitalize effective state programs.

1 Despite its declining budget, FEMA has been successful in developing and implementing
2 earthquake risk reduction tools and disaster-resistant building codes. A noteworthy
3 achievement is the successful development, through cooperative programs with the
4 American Society of Civil Engineers, of earthquake-resistant design standards for new
5 construction, the use of which are referenced in model building codes adopted by local
6 governments and public agencies throughout the Nation. This success, particularly in the
7 areas of lifelines and existing buildings, is now at risk as there is no funding available to
8 maintain efforts and guidance documents.

9
10 FEMA's efforts to promote implementation of available earthquake risk-reduction tools
11 have been less effective. The focus of these efforts has largely been on the public sector,
12 including states and local agencies. However, not all communities have adopted the new
13 building codes and, notably, some communities in the Nation's heartland continue to
14 maintain inappropriate seismic design practices. There has been only limited success in
15 promoting improvements in the seismic resilience, particularly in existing privately
16 owned facilities. In both cases, the lack of success can be tied to the private sector's
17 perception of a lack of adequate return on investment for seismic resilience. There is an
18 opportunity for FEMA to focus on educating decision makers in the private sector, in
19 particular the financial community, on the risks associated with inaction and the benefits
20 of proactive mitigation.

21
22 A number of FEMA's past, highly successful development efforts, including the *NEHRP*
23 *Recommended Provisions for Seismic Regulations for New Buildings and Other*
24 *Structures*, have now been incorporated into national model building codes. FEMA
25 should maintain these essential tools through the cooperative support of not-for-profit and
26 private-sector organizations.

27 28 **2.2 National Institute of Standards and Technology (Member #3)**

29 ACEHR provides two recommendations for NIST:

- 30
31
- 32 • **Recommendation 1:** NIST must secure the funding to effectively carry out its role
33 as the lead agency for the Program and its role in applied research and assistance
34 in implementation of cost-effective mitigation through codes and standards.
 - 35 • **Recommendation 2:** NIST must plan for the development of multi-disciplinary
36 expertise within its own staff and foster relationships with other public agencies
37 and private-sector entities to accomplish the coordinated research to effectively
38 fulfill its obligations.

39 In the years before the 2004 NEHRP reauthorization, NIST's role within NEHRP was
40 relatively minor and not fully realized because of a very low level of funding. FY 2005
41 brought a substantial change to NIST: it became the designated lead agency for NEHRP.
42 Although NIST's direct budget for NEHRP has not been increased, the agency internally
43 reallocated funds to establish the NEHRP Secretariat and hire the Program director. It
44 appears that NIST also has received some support from other NEHRP agencies.

1 Under the reauthorization, NIST was also assigned greater responsibility for applied
2 research and development in earthquake engineering focusing on improving standards
3 and codes for new and existing buildings, infrastructure, lifelines, and construction
4 practices, as well as on measurement and evaluation tools for testing new methods and
5 technologies. The need for this work was documented in the report *The Missing Piece:
6 Improving Seismic Design and Construction Practices*, Applied Technology Council.
7

8 Given the relatively recent shift in the role of NIST to NEHRP lead agency, it is
9 premature to assess fully the effectiveness of the agency. It is clear that NIST has taken
10 seriously the assignment to lead the Program by providing overall coordination, direction,
11 and support of joint efforts consistent with Congressional intent and centered upon
12 objectives defined by the authorizing legislation. Interest from the highest level of the
13 agency is apparent to and appreciated by ACEHR. The office of the NEHRP director is to
14 be commended for its open approach to planning and leveraging resources by actively
15 partnering with the earthquake professional community and by participating in regional
16 consortia. NIST has fostered a strong level of interaction among the agencies
17 participating in NEHRP. There has been notable outreach to interested stakeholders. The
18 process employed in forming and supporting ACEHR, including the method by which
19 nominations were solicited, is one example. The development process for the 2008–2012
20 NEHRP Strategic Plan is another. The future work to develop a comprehensive plan for
21 earthquake engineering research will require a strong commitment to this inclusive
22 philosophy.
23

24 It is apparent that NIST intends to develop a very strong Program. NIST has initiated a
25 dramatic change in direction by going beyond the traditional scope of life safety in
26 individual structures to a much broader approach that includes regional resilience.
27

28 A number of statutory responsibilities have not been met because of a lack of funding.
29 Examples of some of the programs that are not adequately addressed include conducting
30 applied research to enhance model building codes, promoting better building practices
31 among architects and engineers, and working with national standards developers to
32 improve seismic safety standards for new and existing lifelines.
33

34 NIST has begun on a small scale to implement the applied research program, which is
35 intended to be a coordinated program of internal and external projects. The lack of
36 funding, however, has kept the program at a very low level. The initial projects selected
37 for external funding are clearly high-priority projects, but funding is insufficient to
38 develop the staff within NIST needed for the program to be fully effective, and the
39 individual projects are actually small steps.
40

41 The work to assist implementation of cost-effective measures for mitigation of the risk
42 involves many technical disciplines, such as structural, geotechnical, and lifeline
43 engineering, and has to be informed by research on communicating risk information and
44 strategies for adopting mitigation policies, such as economic incentives, well enforced
45 regulations and standards, and insurance. NIST faces a challenge: it must develop
46 sufficient internal expertise to both conduct the internal research and manage the external

1 component of the research program. This broad competence is also necessary to carry out
2 the mandate to promote cost-effective mitigation.

3 4 **2.3 National Science Foundation (Member #4 and Member #5)**

5 ACEHR provides three recommendations for NSF:

- 6
7 • **Recommendation 1:** NSF should enhance its support for multi-disciplinary
8 research related to NEHRP, which can be used as a model for reducing risks
9 associated with other natural and human-induced hazards. In particular, there is an
10 opportunity for the Engineering and Geosciences Directorates to partner with the
11 Social, Behavioral, and Economic Studies Directorate to understand the social and
12 economic factors that promote mitigation measures.
- 13 • **Recommendation 2:** NSF should enhance its support for curiosity-driven basic
14 research, which has been the foundation of many important technical discoveries.
15 Basic research sponsored by NSF educates the next generation of engineers and
16 scientists engaged in earthquake risk reduction. Such support is thus a means of
17 expanding the workforce in earthquake engineering and science.
- 18 • **Recommendation 3:** NSF should solicit support from other federal agencies to
19 leverage the NSF investments in NEES to address critical research needs for the
20 civil infrastructure. To date, research support for NEES has not matched the levels
21 needed by the earthquake community to reduce earthquake risks significantly.

22
23 The NEHRP statutory responsibilities assigned to the NSF are distributed within the
24 agency's Engineering and Geosciences Directorates. Social behavior and economic
25 science research related to NEHRP is currently housed within the Engineering
26 Directorate. In both Engineering and Geosciences, the research funded by the NSF
27 represents a combination of coordinated programs and curiosity-based projects by
28 individual investigators. The NSF has also funded numerous international workshops and
29 post-earthquake investigations.

30
31 Historically, many of the early technical successes of NEHRP were tied to individual
32 researchers conducting curiosity-based research. In the past 20 years, coordinated
33 research projects and research centers have grown to represent a larger portion of the
34 research portfolio within the NSF.

35
36 Over the past 10 years, each of the NSF-sponsored research centers (Mid-America
37 Earthquake Center, (MAE) Multidisciplinary Center for Earthquake Engineering
38 Research (MCEER), Pacific Earthquake Engineering Research (PEER) Center, and
39 Southern California Earthquake Center (SCEC)) has made significant contributions to
40 NEHRP. The Centers serve as models for large, collaborative research efforts and are
41 demonstrated leaders in the development of community-based simulation models - for
42 both earthquake physics and structural response - and integrated outreach to the K-12 and
43 professional communities.

44
45 NEHRP has benefited greatly from multidisciplinary programs within the Earthquake
46 Engineering Research Centers (EERCs) that have combined the contributions of social

1 science, geosciences, and engineering. With the graduation of the EERCs from NSF
2 support, successful long-term programs to support interdisciplinary research have been
3 phased out. Action is needed to encourage and sustain vigorous interdisciplinary
4 activities and to support research activities that benefit from the collaboration among
5 investigators from different disciplines.

6
7 ACEHR is concerned about the level of funding for NEHRP research. Although the NSF
8 made a substantial investment in the infrastructure and management of NEES, the level
9 of funding for research projects has not increased to take advantage of the enhanced
10 research infrastructure and larger pool of researchers. Success levels for NSF proposals
11 related to earthquake engineering and social science research are low, which discourages
12 many researchers from working to reduce risks associated with earthquakes.

13
14 NEES is an important part of NEHRP and a substantial part of the NSF NEHRP research
15 program. Many of the current NSF-sponsored research projects could not have been
16 conducted before the capabilities of the experimental facilities in the U.S. were
17 dramatically enhanced by the NEES equipment sites. The success of NEHRP is therefore
18 linked to the success of NEES activities, including research at the NEES equipment sites,
19 development of information technology (IT) services, and effective outreach projects.
20 ACEHR encourages strong and collaborative management of NEES with attention to
21 engaging the support of other government agencies and industry, and productive
22 education, outreach, and training activities to introduce the next generation of earthquake
23 engineers to the many challenges yet to be resolved.

24 25 **2.4 U.S. Geological Survey (Member #6)**

26 ACEHR provides three principal recommendations for USGS¹:

- 27
28 • **Recommendation 1:** Fully fund ANSS at the level authorized in the current
29 NEHRP legislation. The USGS must make a commitment to work through the
30 DOI and the OMB to ensure that this objective is met.
- 31 • **Recommendation 2:** Proceed with multi-hazard demonstration projects, such as
32 the project being carried out in southern California that was initially funded by
33 Congress in FY 2007. The demonstration projects should expand the multi-hazard
34 scope to include other high-risk areas as part of this effort.
- 35 • **Recommendation 3:** Enhance the coordination of internal and external research
36 activities in earthquake hazards uniformly throughout the United States, and
37 enhance the interaction of the USGS with its NEHRP partners in earthquake
38 engineering (NIST and NSF), earth science (NSF), and earthquake preparedness
39 (FEMA). The noteworthy level of coordination in some geographic areas, such as
40 California, and in some project areas, such as the National Seismic Hazard
41 Mapping project, should be extended to other geographic and project areas.

42
43 The USGS is accomplishing its statutory NEHRP responsibilities in an effective way,
44 both through a host of active partnerships and through the professionalism of its own

¹ Two additional recommendations made by the USGS SESAC, listed on page 12, are also endorsed.

1 agency staff. It seems fair to say that the viability of the USGS Earthquake Hazards
2 Program can be measured by the level of satisfaction among its many stakeholders in the
3 national earthquake community. To its credit, the USGS has done a masterful job of
4 engaging and working with this community—despite NEHRP-specific funding levels
5 widely recognized to be persistently inadequate—to accomplish its first-order NEHRP
6 tasks: (1) provide earthquake monitoring and notification; (2) assess seismic hazards;
7 and (3) conduct research needed to reduce the risk from earthquake hazards nationwide.
8

9 One objective indicator of USGS effectiveness in relation to government performance
10 criteria is the top rating given to the ANSS in 2007 and 2008 by the Investment Review
11 Board of the DOI. “Among 60 major information technology investments, ANSS ranked
12 highest for business value to the mission of the USGS and DOI and lowest for
13 implementation and operational risk” (NEHRP Annual Report, March 2008, page 34).
14 That said, only a small fraction of the authorized and required funding for ANSS has
15 been appropriated.
16

17 The USGS has successfully engaged diverse stakeholders, including seismologists,
18 engineers, emergency managers, and other varied users of earthquake data and
19 information. Many diverse groups are collaborating with the USGS in developing ANSS,
20 as well as in many other aspects of the agency’s NEHRP mission. The effectiveness of
21 these collaborations is enhanced by the openness and responsiveness of USGS to
22 advisory groups such as SESAC, the ANSS National Steering Committee, regional
23 advisory committees, and SCEC, among others.
24

25 While ACEHR’s overall evaluation of the USGS NEHRP collaborations is positive, the
26 Committee believes there are areas where improvements can be made within current
27 levels of funding. The USGS should enhance the coordination of internal and external
28 research activities in earthquake hazards more uniformly throughout the United States.
29 Enhanced USGS interactions with its NEHRP partners in earthquake engineering (NIST
30 and NSF), earth science (NSF), and earthquake preparedness (FEMA) would achieve
31 greater NEHRP coherence. The noteworthy level of coordination in some geographic
32 areas, such as California, and in some project areas, such as the National Seismic Hazard
33 mapping project, can be extended to other geographic and project areas. For example, the
34 USGS, which has an effective capability for public outreach, could involve engineers to
35 help translate earthquake forecasts into implications for the built environment. Similarly,
36 better outreach partnerships with the Earthquake Engineering Research Institute (EERI)
37 and the California Office of Emergency Services could result in conveying a more
38 complete “earthquake story” to the public.
39

40 Examples of NEHRP implementation activities being carried out by the USGS are
41 described in the March 2008 NEHRP Annual Report, the DOI Budget Justification and
42 Performance Information for Fiscal Year 2009, and the SESAC 2008 annual report.
43 Many of these activities were also described to ACEHR at its meetings in May 2007 and
44 October 2007. Core activities of the USGS include earthquake monitoring and reporting
45 of earthquake information through the National Earthquake Information Center (NEIC),
46 ANSS, and the Global Seismographic Network; urban and national seismic hazard

1 mapping; and carrying out innovative earthquake research. Some of the agency's
2 innovative, recent accomplishments include the following:

- 3
- 4 • Development of a new generation of national seismic hazard maps that utilize
5 new ground motion attenuation relations as well as an improved understanding of
6 earthquake hazards, especially in the western United States. These new maps,
7 updated in 2007 for the first time since 2002, are critically important for the
8 development of the 2012 version of the *International Building Code*.
- 9 • Release of a first-ever statewide earthquake rupture forecast model for California.
- 10 • Implementation of multi-hazard demonstration projects in southern California and
11 the Pacific Northwest.
- 12 • Implementation of Prompt Assessment of Global Earthquake Response (PAGER),
13 a system that can readily estimate societal impacts for major domestic and
14 worldwide earthquakes by the NEIC.
- 15 • Success in drilling through the San Andreas fault at a depth of about 2 miles
16 below the ground surface, carried out through the San Andreas Fault Observatory
17 at Depth (SAFOD) project, a multi-year project funded by the NSF and led by
18 scientists from Stanford University and the USGS. The results from this project
19 impact research on earthquake mechanics in a number of fundamental ways.
- 20

21 Under its charter, ACEHR is instructed to consider recommendations of the USGS
22 SESAC in developing its own recommendations. In April 2008, SESAC made the
23 following four primary recommendations (in paraphrased form), representing their
24 highest priorities, for the USGS component of NEHRP:

- 25
- 26 • **SESAC Recommendation 1:** Fully fund ANSS at the level authorized in the
27 current NEHRP legislation. The USGS must make a commitment to work through
28 DOI and OMB to ensure that this objective is met.
- 29 • **SESAC Recommendation 2:** Proceed with multi-hazard demonstration projects,
30 such as the project being carried out in southern California that was initially
31 funded by Congress in FY 2007. The demonstration projects should expand the
32 multi-hazard scope to include other high-risk areas as part of this effort.
- 33 • **SESAC Recommendation 3:** Develop a comprehensive monitoring, analysis,
34 and research program to study the significance of episodic tremor and slip events.
35 It is especially important to better understand the significance of this phenomenon
36 with respect to changes of earthquake probability.
- 37 • **SESAC Recommendation 4:** Increase the number of research scientists actively
38 engaged in the Earthquake Hazards Program. Over the past two decades, there has
39 been a dramatic decrease in the number of USGS scientists working to fulfill the
40 agency's NEHRP mission. It is essential to reverse this trend to meet both the
41 challenges and opportunities facing the Earthquake Hazards Program.
- 42

43 ACEHR endorses these recommendations of SESAC, amplifying in particular
44 Recommendations 1 and 2. ACEHR notes that the issue of inadequate staffing is a cross-
45 cutting one affecting all four NEHRP agencies. Another cross-cutting issue is the
46 importance of interdisciplinary interactions. ACEHR believes each agency must ask

1 itself: what is not getting done, or not getting done effectively, because of a lack of
2 relevant multidisciplinary expertise within its NEHRP workforce? In the case of USGS,
3 relevant in-house professional expertise might include, for example, social science,
4 structural engineering, or other non-earth science specializations. To clarify, ACEHR's
5 recommendation is not to duplicate core competencies in each agency but rather to
6 advocate some useful presence of multidisciplinary expertise in each agency for carrying
7 out its NEHRP mission more effectively.
8
9

1 **3. Management, Coordination, and Implementation of NEHRP (Member #2)**

2
3 ACEHR provides one recommendation related to Management, Coordination, and
4 Implementation

- 5
6 • Consistent with the change in the leadership of the NEHRP, ACEHR recommends
7 that USGS delegate post-earthquake investigation leadership to NIST, reconsider
8 the organization and deployment of reconnaissance teams, and sponsor
9 publication of discipline-oriented interactive media that archived collected data. .

10
11 The 2004 reauthorization of NEHRP established an expanded ICC made up of the
12 directors of NIST, FEMA, the NSF, the USGS, the OMB, and the White House OSTP.
13 The Congressional desire to encourage a higher level of coordination and collaboration
14 between the agencies, their budgeting processes, and the President’s science initiatives
15 appears to have been well received and has resulted in very positive changes to the
16 Program. The ICC has accepted briefings from the ACEHR chair on two occasions and
17 has been receptive to ACEHR’s observations. At the last briefing, the President’s Science
18 Advisor declared that ACEHR was “preaching to the choir,” indicating that there is
19 strong support for the Program and general agreement on what needs to be done, and
20 pointed out that the ACEHR recommendations are consistent with the President’s
21 National Science and Technology Council report *Grand Challenges for Disaster*
22 *Reduction*. ACEHR looks forward to a continuous dialogue with the ICC.

23
24 After 25 years of good, individual progress by the NEHRP agencies, the Program now
25 also benefits from a high level of interagency collaboration and a common focus. The
26 2007 annual report offered the first signs of this benefit and the 2008–2012 NEHRP
27 Strategic Plan outlines a wide variety of strategic priorities, each with a designated
28 agency lead, and carries the expectation that the other agencies will do their parts in a
29 coordinated and collaborative manner that leverages synergy and minimizes duplication
30 of effort.

31
32 Consistent with the change in the leadership of the NEHRP, ACEHR believes that the
33 Program would benefit from a similar change in leadership related to post-earthquake
34 investigations. Section 11 of Public Law 108-360 establishes a post-earthquake
35 investigation program within USGS that involves NSF, NIST, as well as other federal
36 agencies and private contractors. ACEHR fully supports the need for post-earthquake
37 investigation, believes the USGS Circular 1242 should be updated, and sees the following
38 opportunities for significantly improving our ability to gather and utilize important
39 perishable data after an earthquake.

- 40
41 • In addition to the current practice of dispatching an interdisciplinary
42 investigation team for a rapid, overarching assessment of earthquake
43 characteristics and effects, emphasis should be placed on discipline-oriented
44 teams to investigate each facet of the earthquake. Each team should be funded
45 by its related organization or agency. Teams should be identified to investigate

1 earth science, geo-engineering, lifelines, structural, social, and economic aspects
2 of each major event.

- 3 • USGS should delegate leadership to coordinating post-earthquake
4 reconnaissance efforts to the lead NEHRP agency, NIST. NIST should serve as a
5 single point of coordination, without any discipline-specific individual
6 responsibility, to ensure that all key aspects of an event are captured in a
7 balanced manner. Staff and funding must be provided to refine the response
8 program, identify available participants, and maintain a state of response
9 readiness.
- 10 • The results of the investigations and related research should be gathered and
11 archived in the Post-Earthquake Information Management System (PIMS) and
12 published in a set of discipline-oriented interactive media that archive collected
13 data related to the immediate and long-term impacts of the event.

14
15 ACEHR recommends that this change in structure be incorporated during the next
16 NEHRP reauthorization cycle.

17
18 ACEHR is deeply concerned about the continuing withering of funds for the Program.
19 At approximately \$100 to \$200 million per year, NEHRP funding has been essentially
20 flat or below inflation levels for the past 30 years. In 2003, EERI's *report Securing*
21 *Society Against Catastrophic Earthquake Losses: A Research and Outreach Plan in*
22 *Earthquake Engineering* determined that \$330 million per year was needed, although
23 just the opposite is happening. There is evidence that funds recently appropriated for the
24 Program have in some cases been diverted. ACEHR recognizes that this Program is a
25 small part of the federal budget, so small that it does not have line items in the
26 Congressional budget. Funding decisions appear to be made at the department and
27 agency level. ACEHR appreciates the need for balance in the budgets for each
28 department and agency and their need to adhere to the President's priorities. The
29 Committee respectfully submits that more priority be given to the Program and that full
30 funding at authorized levels be appropriated and that the program redo the EERI report to
31 determine the true cost of implementing the strategic plan.

32
33 The ACEHR understands that a process has been developed for sharing information
34 related to NEHRP program budgets and coordinating areas of common activities. The
35 Committee believes that the availability of a fully supported Strategic Plan and a
36 coordinated budgeting process will lead to opportunities to expand appropriations and
37 achieve significant added value.

38
39 While implementation of NEHRP's new management structure is proceeding more
40 slowly than was hoped for due to a lack of funding, the ACEHR sees no need to adjust
41 any of the components. The ACEHR is pleased that NIST intends to dedicate 50 percent
42 of its NEHRP research funds to an external grants program, and encourages NIST to
43 follow through on this plan. Although much of the basic "missing link" research can be
44 done in the NIST laboratories, there is a strong need for research to also be carried out at
45 the various universities and professional organizations that have been active participants
46 in the Program.

1 The ACEHR has developed into a collaborative group of earthquake professionals. The
2 Committee appreciates the diversity of participants and balanced perspectives that are
3 represented. The members of ACEHR appreciate the opportunity to review the Strategic
4 Plan during its development and would like that same opportunity for future Strategic
5 Plans, annual reports, and other documents produced by the NEHRP Secretariat. The
6 ACEHR also believes that it would benefit from more representation from the lifelines
7 and financial industries, as well as from urban planners. The ACEHR also would benefit
8 from the ability to use eTechnology to conduct its deliberations from remote sites and
9 within public view.

10

11

1 **Appendix —Trends and Developments in Science and Engineering**

2 3 **A. Social Sciences (Member #7)**

4 5 ***A.1 General***

6 The field of risk analysis has assumed increasing importance for the social sciences in
7 recent years given the concern by both the public and private sectors in safety, health, and
8 environmental problems. There is a need for more detailed studies on risk assessment,
9 taking into account the built-in environment to complement the research that has been
10 undertaken on hazard assessment (the nature of the earthquake risk).

11 12 ***A.2 Risk Assessment***

13 Risk assessment encompasses studies that estimate the chances of a specific set of events
14 occurring and/or their potential consequences. Scientists and engineers need to provide
15 the users of these data with a picture of what is known regarding the nature of a particular
16 risk and the degree of uncertainty surrounding these estimates. They also have to be
17 sensitive to their role as assessors of these estimates. It is not uncommon for the public to
18 hear Expert 1 and Expert 2 disagree about the level of risk. There may be many different
19 reactions to these conflicting reports. One layperson may decide that he or she cannot
20 rely on the judgment of any expert. Another may decide to focus on the expert supporting
21 his or her own view of the risk. Someone else may seek out the views of other experts to
22 see if there is a degree of consensus on the nature of the risk.

23
24 A key question to be addressed in undertaking risk assessment is the degree of
25 uncertainty regarding both probability and outcomes. It is much easier to construct such a
26 curve for earthquakes than it is for terrorist activities. However, even for these more
27 predictable accidents or disasters, there may be considerable uncertainty regarding the
28 likelihood of the occurrence for earthquakes and the resulting damage. Providing
29 information on the degree of uncertainty associated with risk assessments should increase
30 the credibility of the experts producing these figures. There is also a need for experts to
31 state the assumptions on which they are basing their estimates of the likelihood of certain
32 events occurring and the resulting consequences. The nature of these assumptions should
33 enable the general public to gain a clearer picture as to why there is so much ambiguity
34 surrounding estimates of some risks and much less uncertainty on others

35 36 ***A.3 Risk Communication***

37 There is a need to present information to individuals so that they appreciate the meaning
38 of low and high probabilities. Laypersons are not likely to process these data in ways that
39 scientists and engineers would like them to. Most people believe small numbers can be
40 easily dismissed, while large numbers get their attention. By stretching the time frame
41 over which the probability of an extreme event is presented, one may get people to pay
42 attention to an event that they would otherwise ignore. The following example illustrates
43 how the same probability, one presented using a long time horizon and the other using a
44 short one, can influence the adoption of protective measures. If a company is considering
45 earthquake protection over the 25-year life of its plant, managers are far more likely to

1 take the risk seriously if they are told the chance of at least one earthquake occurring
2 during the entire period is 1 in 5 rather than learning that it is 1 in 100 in any given year.

3 4 **A.4 Achievements**

5 Since the inception of NEHRP, NSF has been responsible for funding basic and applied
6 research on the societal dimensions of earthquakes, including research on earthquake
7 mitigation, preparedness, response, recovery, and related topics, such as risk assessment
8 and communication and earthquake loss reduction policy.

9
10 In 2004, the National Research Council Committee on Disaster Research in the Social
11 Sciences was charged with assessing the importance and contributions of social science
12 research sponsored over the years by NEHRP and with identifying new frontiers for
13 research. Again, the vast majority of this work was supported by NSF. The Committee's
14 report, *Facing Hazards and Disasters: Understanding Human Dimensions* (National
15 Research Council, 2006), highlighted numerous ways in which NEHRP-sponsored
16 research has improved our understanding of the societal aspects of earthquakes and other
17 threats, including technological disasters and terrorism. The report also recognized the
18 need for new research on a range of hazard-related topics. Examples highlighted in the
19 report include research to identify better mechanisms for intervening into the dynamics of
20 hazard vulnerability; to encourage the adoption of mitigation measures and evaluate the
21 effectiveness of existing measures; to assess the impacts of changes over time in hazard-
22 related laws, policies, and programs; and to better understand the challenges associated
23 with near-catastrophic and catastrophic disaster events. Also emphasized were the need
24 for funds to support data archiving, preservation, and sharing; stronger efforts directed to
25 the development of a disaster research workforce; and research on enhancing
26 multidisciplinary and interdisciplinary collaborations in hazard-related fields.

27 28 **A.5 Challenges**

29 There is a need for agencies concerned with implementation of NEHRP to fund research
30 that advances the understanding of the social, psychological, and economic factors that
31 encourage or inhibit residents and businesses from investing in mitigation measures. One
32 key document published by the National Science and Technology Council's
33 Subcommittee on Disaster Reduction, *Grand Challenges for Disaster Risk Reduction*
34 (Subcommittee on Disaster Reduction, 2005), calls explicitly for research that makes it
35 possible to provide hazard and disaster information when and where it is needed (Grand
36 Challenge#1); develop hazard mitigation strategies and technologies (Grand Challenge
37 #3); recognize and reduce critical infrastructure vulnerabilities (Grand Challenge #4);
38 assess disaster resilience (Grand Challenge #5); and promote risk-wide behavior (Grand
39 Challenge #6). None of these Grand Challenges can be addressed without the kind of
40 research in the social, economic, and policy sciences that NSF has historically supported.

41
42 *Securing Society Against Catastrophic Earthquake Losses*, a consensus report developed
43 by EERI (2003), contains an entire section devoted to needed research that can result in
44 enhancing community resilience in the face of the earthquake threat. The topics identified
45 as requiring additional research include factors that drive societal and community
46 vulnerability to earthquake hazards; the relative cost and effectiveness of alternative risk

1 management policies; earthquake impacts on households, businesses, and communities,
2 along with strategies for reducing those impacts; demands that earthquakes place on
3 response and recovery systems, as well as how to improve such systems; and factors that
4 affect the adoption and implementation of risk management practices.

5
6 One way to encourage this research is to promote a risk analysis framework for future
7 research in the hazards area. As noted above, the field of risk analysis has assumed
8 increasing importance for the social sciences in recent years given the concern by both
9 the public and private sectors in safety, health, and environmental problems. Risk
10 analysis encompasses three interrelated elements: risk assessment, risk perception, and
11 risk management.

12
13 Successful risk analysis requires scientists and engineers to undertake *risk assessments* to
14 characterize the nature and uncertainties surrounding a particular risk. One also needs
15 social scientists to characterize the factors that influence *risk perception* by individuals,
16 groups, and organizations. While traditional risk assessment focuses on losses that are
17 often measured in monetary units, risk perception is concerned with the psychological
18 and emotional factors that have been shown to have an enormous impact on behavior.
19 There is a need to develop *risk management* strategies that involve risk communication,
20 economic incentives, standards, and regulations for managing these risks. Given the
21 challenges in processing information on these risks, as well as the interdependencies
22 between individuals and firms which create negative externalities, funding should support
23 research that examines strategies for reducing future losses efficiently while addressing
24 equity and affordability issues.

25 26 **B. Earth Science (Member #6)**

27 28 ***B.1 General***

29 This section addresses aspects of earthquake seismology, strong-motion seismology, and
30 developments in associated programs relevant to NEHRP. The knowledge, tools, and
31 practices in this arena overlap science and engineering—especially relating to design
32 ground motions, where scientists and engineers work closely together. They also overlap
33 science and emergency management.

34
35 Although there currently is no scientific capability to predict within narrow bounds the
36 size, location, and occurrence time of future earthquakes, there is much that can now be
37 predicted with some degree of certainty. For example, the likely locations and sizes of
38 future earthquakes that threaten major metropolitan areas in many parts of the Nation are
39 reasonably well known, and detailed predictions can be made of the severity of ground
40 shaking that will result from these earthquakes, as well as the effects of the shaking on
41 buildings, infrastructure, and facilities.

42
43 Seismologists currently emphasize three basic approaches to meeting societal needs for
44 earthquake loss reduction: the analysis and mapping of seismic hazards, ground-motion
45 forecasts for scenario planning, and rapid post-event notification. At the same time, there
46 is vigorous research aimed at: (1) integrating seismology, geology, geodesy, and fault

1 mechanics to develop a comprehensive physics-based understanding of earthquake
2 phenomena; (2) achieving capabilities for earthquake *forecasting*, based on rigorous
3 statistical studies of space-time patterns of earthquake occurrence; and (3) developing
4 reliable methods for providing *earthquake early warning* (real-time alerting once an
5 earthquake is in progress and before energetic seismic waves arrive).
6

7 ***B.2 Achievements and Challenges***

8 The March 2008 NEHRP annual report, the April 2008 SESAC report, and other NEHRP
9 reports summarize many notable achievements and developments in earth science
10 relevant to NEHRP goals. Some selected items are presented to give the reader a sense of
11 stimulating developments and important strides being made. The ACEHR also includes
12 perspectives on some programmatic aspects of NEHRP that relate to these earth science
13 developments, including challenges.
14

15 *Episodic tremor and slip* — One of the most exciting geophysical discoveries since the
16 plate tectonics paradigm of the 1960s is the documentation of non-volcanic tremor and
17 associated deep, episodic aseismic slip events in a number of subduction zones around
18 the world. Now referred to as ETS (episodic tremor and slip), this remarkable
19 geophysical phenomenon has been particularly well-documented in the Cascadia
20 subduction zone that threatens the Pacific Northwest and western British Columbia.
21 Deep episodic tremor has now also been found beneath the San Andreas fault in central
22 California. Achieving an improved understanding of possible relationships between ETS
23 events and potential future large earthquakes is an important and scientifically intriguing
24 challenge.
25

26 *Ground motion prediction modeling* — An important development for ground motion
27 prediction modeling, as well as for probabilistic seismic hazard analysis and earthquake
28 engineering design, was the completion in 2007 of the PEER Center Next Generation
29 Attenuation (NGA) models for shallow crustal earthquakes in the western U.S.
30 Unfortunately, these models still suffer from sparse near-source recordings of strong
31 ground motion. The new models provide improved reliability in the prediction of the
32 median levels of ground motions, but their variability has not been reduced. The site-to-
33 site variability in ground motions depends not only on the shallow geological structure,
34 but also on features of the fault rupture process itself, such as rupture directivity, that
35 cause spatial variations in ground motion levels. Dynamic models may provide an
36 important approach to understanding the physical limits on strong ground motion levels.
37 This may help to quantify the shape of the distribution of extreme ground motion values,
38 which is difficult to discern in the strong motion data but has a large impact on seismic
39 hazard analyses and design.
40

41 *Earthquake early warning* — During the last few years, significant progress has been
42 made outside of the U.S. in the development of earthquake early warning systems,
43 designed to provide alerts ahead of the arrival of strong shaking in heavily populated
44 areas. Such systems are currently operational in five countries (Japan, Mexico, Turkey,
45 Italy, and Romania) and are under development in six others (Taiwan, Iceland,
46 Switzerland, Greece, and Egypt). In the U.S., pre-prototype earthquake early warning

1 tests are being conducted by member institutions of the California Integrated Seismic
2 Network (CISN), a regional component of ANSS, as part of a 3-year program funded by
3 the USGS. The assessment of SESAC is that much work remains to be done before this
4 technology could be confidently used as part of a national program for earthquake public
5 safety.

6
7 *Multihazards demonstration project in southern California* — An important new thrust
8 for the USGS Earthquake Hazards Program is a Multi-Hazard Demonstration Project
9 (MHDP) in southern California, which will demonstrate how hazards science can be used
10 to improve resiliency to a range of natural disasters. During 2007–2008, the major
11 activity of the MHDP is the development of an earthquake planning scenario for southern
12 California. The scenario assumes a magnitude 7.8 earthquake on the southern San
13 Andreas fault, with fault rupture beginning near the Salton Sea and propagating
14 northwestward past San Bernardino to just north of Palmdale. Damage assessments from
15 the scenario will be incorporated into the November 2008 “Great Southern California
16 ShakeOut” (a community outreach activity) and the Golden Guardian exercise for
17 emergency managers in the 8 counties and more than 200 cities of southern California
18

19 *California statewide earthquake rupture forecast* — In 2008, the USGS and its partners
20 are delivering the first-ever statewide earthquake rupture forecast model for California.
21 This model, developed collaboratively with the California Geological Survey (CGS) and
22 the SCEC, provides input to the national seismic hazard maps and will be used to update
23 earthquake insurance premiums in the state.
24

25 *Large-scale, geographically distributed collaborations* — Multi-institutional partnering
26 is increasingly enabling the development and sharing of seismological data, geophysical
27 models, and computational tools by a broad community of investigators. Examples are
28 ANSS; the SCEC Community Modeling Environment, providing a virtual collaboratory
29 for knowledge management, hypothesis formulation and testing, data conciliation and
30 assimilation, and prediction; and the National Center for Engineering Strong-motion
31 Data, a new “one-stop” access facility created by the USGS Earthquake Program and the
32 CGS Strong-Motion Instrumentation Program, which not only makes strong ground
33 motion databases widely available but will also support and integrate international data
34 collection activities currently performed by the COSMOS Virtual Data Center.
35

36 *NSF/Geosciences synergy with USGS* — Synergy between NSF- and USGS-funded
37 programs is becoming increasingly critical for the success of data acquisition, data
38 processing/archiving/distribution, and seismological research relevant to NEHRP goals.
39 Examples include: (1) joint funding of SCEC III, the current 5-year phase of SCEC; (2)
40 joint operation of the GSN; and (3) contributions to NEHRP goals by all three
41 EarthScope components (USArray, SAFOD, and Plate Boundary Observatory (PBO)).
42 One challenge is to achieve greater coherence, where feasible, between NSF and USGS
43 strategic planning as it relates to NEHRP goals.
44

45 *NSF/EarthScope’s USArray* — The first 400-station complement of USArray (intended
46 primarily to study deep earth structure) was completed in 2007, with a footprint covering

1 a large part of the western U.S. (Washington, Oregon, California, Nevada, and the
2 western parts of Montana, Idaho, Utah, and Arizona). Many of these non-NEHRP
3 stations fill in large gaps in regional seismographic coverage of the western U.S., which
4 unfortunately will reappear when the transportable stations progressively move after 18–
5 24 months. Lack of ANSS funds to “adopt” a sizeable subset of these high-quality
6 broadband stations to fill geographic holes in the system will mean a missed opportunity
7 for NEHRP.

8
9 *USGS’s ShakeMap and FEMA’s HAZUS* — The ability to integrate ANSS ShakeMap
10 data with HAZUS for loss estimation is proving to be an extremely valuable tool, both for
11 rapid post-event impact assessment and for scenario planning. Coordination between the
12 USGS and FEMA to develop and improve ground-motion-based HAZUS loss estimates
13 is a NEHRP success story. Challenges still remain for automating the rapid production of
14 HAZUS results, particularly in large metropolitan areas, when ShakeMap data are
15 generated by a moderate to large earthquake.

16
17 *The Need for Full Funding of ANSS* — The USGS and its ANSS partners now produce in
18 real-time, or near-real time, an unprecedented suite of Web-based information products
19 on earthquake effects that assist disaster response agencies. ShakeMap, ShakeCast, and
20 the PAGER system provide specific, detailed information on earthquake effects that
21 could not have been imagined at the time of the 1989 Loma Prieta, 1994 Northridge, and
22 1995 Kobe earthquakes. The ability of the USGS to provide real-time earthquake data
23 and products that enable rapid and efficient local, state, and federal response is dependent
24 on the continued expansion of ANSS and funding to maintain and sustain operations.
25 Progress in engineering seismology is being hindered by the inadequacy of strong motion
26 recording systems throughout the U.S. Even in seismically active regions such as
27 California and the Pacific Northwest, there are not enough recorded ground motion time
28 histories for use in representing earthquake ground motions for structural design. The
29 situation is even worse elsewhere. A particularly important need for strong motion
30 recordings is to understand the seismic response of urban regions. There are not dense
31 enough urban strong motion arrays to allow an understanding of the spatial variations in
32 ground motions (and damage) that characterize most earthquakes. For a host of
33 compelling reasons, full funding of ANSS is urgently needed.

34
35 *Human resource problem* — The April 2008 SESAC report calls attention to a critical
36 human-resource problem within the USGS. The problem afflicts other NEHRP agencies
37 as well. Indeed, an aging workforce and decreasing numbers of students pursuing careers
38 in NEHRP-related science could foreshadow a major human resource problem for
39 NEHRP. In the case of the USGS, its ability to meet a number of mission-critical tasks is
40 seriously threatened by the steady decrease in the number of research scientists actively
41 engaged in the Earthquake Hazards Program—from a high of over 400 staff supported in
42 the 1980s to 220 at the end of 2007.

43

1 **C. Geotechnical Earthquake Engineering (Member #8)**

2
3 ***C.1 General***

4 Geotechnical earthquake engineering is traditionally placed between the disciplines of
5 earth science and structural engineering, although it interfaces with all earthquake-related
6 disciplines given its breadth. As a result of the geotechnical engineering profession's
7 placement and its size relative to earth science and structural engineering, its true impact
8 on earthquake resilience can be underappreciated at times. However, advancements in
9 earthquake resilience require incorporation of important geotechnical effects of
10 earthquakes, such as surface fault rupture, seismic site effects, liquefaction, seismic
11 instability, and soil-foundation-structure interaction. As the criticality of a multi-
12 disciplinary approach to addressing earthquake hazards (as well as other hazards) is
13 recognized, geotechnical engineering as a natural linkage between disciplines can provide
14 a critical path forward in increasing earthquake resilience.

15
16 ***C.2 Achievements***

17 The important effects of local ground conditions on earthquake ground motions is now
18 widely appreciated and incorporated in the International Building Code. Liquefaction is
19 also widely recognized as a critical hazard, and liquefaction triggering procedures are
20 fairly well established for many soils. Potential seismic slope instability hazards are
21 mapped by several state geologic surveys, and dam/waste regulatory agencies have
22 established comprehensive evaluation procedures. Geotechnical engineers have led the
23 development of quantitative GIS-based documentation of the effects of earthquakes.

24
25 ***C.3 Issues and Challenges***

26 Significant challenges remain, however, in the geotechnical earthquake engineering and
27 related professions. Earthquake science and engineering should grow more
28 interconnected and interdisciplinary. NEHRP can shepherd this emerging trend.
29 Geotechnical engineering needs to be an integral part of multi-disciplinary research.
30 Although NIST's establishment of an external grant program fills a critical gap between
31 NSF-funded basic research and applied research needed for effective implementation, the
32 NIST earthquake research program should include the effective transfer of geotechnical
33 engineering knowledge.

34
35 Levee and flood protection system reliability, including their seismic performance, must
36 be addressed by the Nation. Improved hazard maps for ground failure and methods for
37 characterizing the magnitude and distribution of ground movements triggered by
38 earthquakes are needed. Better methods are needed for predicting liquefaction impact on
39 geographically distributed systems. Analytical procedures have been developed for
40 predicting ground deformation and characterizing structural response to ground
41 movements. Research facilities, such as NEES, can be employed to clarify ground
42 movement and soil-structure interaction for practical purposes. In particular, the
43 profession lacks clear guidance on the potential impact of soil-structure interaction on
44 building performance.

1 High-end computing coupled with enhanced visualization software is transforming the
2 manner in which we evaluate seismic performance. Supporting efforts need to continue
3 toward characterization of geo-material properties and the uncertainty inherent in any
4 seismic problem. Field and laboratory experiments are required to advance earthquake
5 science and engineering through innovative site and material characterization
6 technologies. The geotechnical information collected following earthquakes should be
7 archived as well and made available to researchers, engineers, planners, and emergency
8 responders. Incorporation of advanced technologies and imaging techniques, such as
9 LiDAR, in post-earthquake reconnaissance can strengthen the lessons that the profession
10 can glean from future earthquakes.

11
12 Performance-based earthquake engineering requires consensus methods for selecting and
13 scaling ground motions to represent the seismic hazard at a project site and quantitative
14 data that translates calculated engineering responses into damage and then deaths, dollars,
15 and downtime. Without full implementation of ANSS, the spatial variability of ground
16 shaking due to local geology cannot be refined or utilized optimally in post-earthquake
17 emergency response. Geotechnical structures, including downhole arrays, should be
18 better instrumented. Better models of ground shaking near faults and in the eastern and
19 central U.S. are required. Owners should be motivated to better understand the special
20 nature and needs of their project and engage engineers to design for the desired level of
21 performance according to a site-specific hazard assessment. While NEHRP should
22 advance codes, the Program should advance tools that move the profession toward true
23 performance-based design.

24 25 **D. Structural Earthquake Engineering (Member #9)**

26 27 ***D.1 General***

28 Recent developments in structural engineering include efforts to develop performance-
29 based engineering and methods to develop tools for health monitoring and rapid
30 assessment of structural condition following earthquakes.

31
32 Performance-based engineering comprises two primary parts: development of: 1)
33 practical and reliable means of predicting the probable behavior of buildings and
34 structures in earthquakes and the effects of this behavior on society; and, 2) technologies
35 that can effectively control and limit earthquake damage and consequences in both new
36 and existing structures.

37
38 Following earthquake disasters, society has a need to identify those buildings and
39 structures that are safe for continued occupancy and for use as centers for recovery, as
40 well as those structures which are damaged to an extent that renders them unsafe or
41 otherwise unusable. In the past, assessment of structural condition could be conducted
42 only through the efforts of individual engineers with the knowledge and skills to rapidly
43 assess damage and make reliable judgments as to structural condition. In a large disaster,
44 such as a major earthquake affecting Charleston, Los Angeles, Memphis, Seattle, San
45 Francisco, or Salt Lake City; thousands of buildings and lifeline structures will be
46 affected. There are not enough sufficiently trained engineers to perform the needed

1 assessments in a rapid manner. Failure to identify safe, useable, and unusable structures
2 places citizens in the affected regions at greater risk and hinders the ability of government
3 to marshal the resources necessary to speed aid to the affected region.
4

5 ***D.2 Achievements***

6 The ability to predict before an earthquake occurs how individual buildings and
7 structures, as well as entire portfolios of buildings and structures, will behave is essential
8 to any program intended to increase society's earthquake resiliency. Without this
9 capability, it is impossible to understand the risks or to effectively allocate resources to
10 mitigate these risks. Twenty years ago, such performance assessments could be made
11 only by a very few expert engineers who had the knowledge and judgment to effectively
12 perform this task. These experts numbered far too few to permit widespread and routine
13 assessment of the risks.
14

15 The development and introduction of HAZUS approximately 10 years ago afforded the
16 capability to realistically assess earthquake risks at a community level, but did not
17 provide engineers with the ability to reliably predict the likely performance of individual
18 structures, hindering their ability to effectively mitigate the risks. Work undertaken at the
19 three NSF-sponsored earthquake engineering research centers has begun to provide
20 engineers with the tools needed to reliably predict the performance of individual
21 buildings and structures in terms of the likely damage and, more importantly, the human,
22 economic, and societal losses resulting from this damage. Many fledgling simulation
23 tools and some significant amounts of data have been developed that enable the use of
24 these tools to predict the performance of some classes of structures. These tools are
25 slowly being disseminated to the practicing professionals in useable form.
26

27 Once earthquake risks to society have been identified, it is essential that engineers have
28 cost-effective construction technologies available that are capable of limiting damage to
29 acceptable levels if they are to be effectively controlled. Twenty years ago, seismic
30 isolation and passive energy dissipation technologies were known and available but
31 proved to be prohibitively expensive to implement in many structures. Structural
32 engineering researchers have focused much attention in recent years on the development
33 of alternative damage-resistant structural systems that are more economical to implement.
34 Some noteworthy success has been achieved, including development and adoption by the
35 building codes of buckling-restrained braced steel frames and precast-hybrid concrete
36 frames, both damage-resistant systems. In addition, new methods of constructing
37 traditional structural systems are becoming available, providing a capability to design and
38 build a more damage-resistant environment. Work is continuing in both areas. Perhaps
39 equally important, researchers are also developing methods to reduce risk associated with
40 a variety of nonstructural components and systems, including storage racks, ceiling
41 systems, interior partitions, electrical systems, and similar items. This is particularly
42 important because most of the economic losses associated with recent U.S. earthquakes
43 have resulted from nonstructural rather than structural damage.
44

1 ***D.3 Issues and Challenges***

2 Substantial additional work is required to enable effective implementation of
3 performance-based engineering procedures. Needs include the following:

- 4
- 5 • Development of fragilities and consequence functions for the many types of
6 structural systems and nonstructural components found in building structures so
7 that the performance of new and existing buildings and structures and the losses
8 associated with this performance can be accurately predicted.
- 9 • Development of reliable means of predicting structural collapse so that existing
10 structures that are truly hazardous can be identified and so that new structures can
11 be reliably designed to protect life safety.
- 12 • Continued development of performance-based engineering tools that will enable
13 engineers and other design professionals to reliably assess structural performance
14 and design buildings and structures for improved performance.
- 15 • Development of practical and effective structural systems that can be used to
16 minimize damage and loss in both new and existing structures.
- 17 • Development of tools that will enable the data collected from ANSS and
18 privately-owned health monitoring instruments in buildings to instantaneously
19 collect, process, and interpret the data so as to make rapid assessments on
20 structural condition.
- 21 • Education of the design professional community so that they can effectively use
22 these new tools.

23 **E. Lifelines Earthquake Engineering (Member #5)**

24

25 ***E.1 General***

26 Lifelines provide the networks for delivering resources and services necessary for the
27 economic well-being and security of modern communities. They are frequently grouped
28 into six principal systems: electric power, gas and liquid fuels, telecommunications,
29 transportation, waste disposal, and water supply. Taken individually, or in aggregate,
30 these systems are essential for emergency response and restoration after an earthquake,
31 and are indispensable for community resilience.

32

33 ***E.2 Achievements***

34 Significant advances in lifeline earthquake engineering have been made in high-
35 performance computational models that simulate complex networks. These models put
36 out highly graphic, detailed scenarios that enable modelers and associated emergency
37 personnel to visualize a wide range of responses from an entire lifeline system to a
38 specific part of that system. By running multiple scenarios, with and without
39 modifications of the system, operators can identify recurrent patterns of response and
40 develop an overview of potential performance, helping them plan for many eventualities
41 and improving their ability to improvise and innovate in the event of a real temblor.

1 Major assessments of system-wide earthquake performance have been undertaken by
2 water utility companies, including the East Bay Municipal Utility District, Los Angeles
3 Department of Water and Power, and the San Francisco Public Utilities Commission, as
4 the basis for planning and rehabilitation of their systems. These assessments have used
5 advanced system simulations and seismic hazard characterization using the results of
6 NEHRP-supported research and development programs.

7
8 Lifeline system disruption has a direct effect on business losses that, in turn, have
9 multiple related effects on other businesses. There is a growing body of research and
10 applications associated with the economic and social consequences of lifeline damage
11 and loss of functionality. The economic and community consequences of earthquake
12 damage are being integrated with system simulations to create models and a modeling
13 process that link the earthquake response of lifelines through system reliability to
14 regional economic and social impacts.

15
16 A significant trend in lifeline and geotechnical earthquake engineering has been the
17 implementation of large-scale and centrifuge testing facilities to assess lifeline response
18 to earthquake loading. Examples include the large-scale and centrifuge experiments
19 currently underway at NEES, as well as shake-table and full-scale tests at various
20 universities, including those supported by the EERCs.

21
22 Both the process and specific applications being developed for lifeline earthquake
23 engineering are transferable to other hazards, including natural hazards and human
24 threats. Studies of lifeline system response to the World Trade Center Disaster have
25 emphasized the remarkable degree of interdependence that exists among lifeline systems.
26 The investigation of such interdependencies has been a cornerstone of lifeline earthquake
27 engineering research and modeling. There is considerable benefit being derived from
28 lifeline earthquake engineering for improving the security of civil infrastructure against
29 natural hazards as well as major accidents and terrorism. Because of the cascading effects
30 that can result from lifeline disruption, local lifeline damage can rapidly expand to have a
31 regional, national, and even an international impact. Examples include the disruption of
32 the New York Stock Exchange due to loss of telecommunications and electricity after the
33 World Trade Center Disaster and the impact of Hurricane Katrina on the U.S. petroleum
34 and natural gas delivery infrastructure, affecting the worldwide cost of both commodities.

35
36 Since Hurricane Katrina, there has been a notable shift in emphasis from protecting
37 critical infrastructure to ensuring that communities are resilient. Understanding and
38 planning for effective lifeline response after extreme events is a key part of developing
39 community resilience. NEHRP-supported programs have led the way to understanding
40 and planning for the disruption of critical lifeline services and to providing important
41 tools and modeling procedures for multi-hazard applications.

42 43 ***E.3 Issues and Challenges***

44 Substantial work is needed to address lifeline system preparedness, improve performance,
45 and coordinate improvements to achieve enhanced community resilience. Significant
46 issues and areas of high priority include:

- 1 • NEHRP lost its only dedicated source of support for implementing lifeline risk
2 reduction measures in practice when FEMA funding was terminated in 2007 for
3 the American Lifelines Alliance. Support for implementation needs to be restored,
4 with a new model for the collaborative setting of priorities and programmatic
5 support for measures to mitigate lifeline earthquake hazards.
- 6 • A national workshop should be convened to obtain balanced and multidisciplinary
7 advice from the lifelines community on the development of a coordinated
8 approach to lifeline earthquake risk reduction. The workshop should address the
9 multi-hazard aspects of lifeline performance and should result in a consensus on
10 how NEHRP activities can advance multi-hazard resilience. NIST is the most
11 appropriate host of such a workshop.
- 12 • Consistent with the Grand Challenges, NEHRP-related activities to improve
13 lifeline earthquake engineering should support efforts to recognize and reduce the
14 vulnerabilities arising from interdependencies among different lifeline systems.
- 15 • Support should be sought for critical lifelines from governmental agencies not
16 part of NEHRP. Foremost among the departments with agencies with a vested
17 interest in the security and functionality of lifelines are the DHS, the Department
18 of Energy, the Department of Transportation, and the Department of Defense.
- 19 • Lifeline earthquake research and development should contribute to multi-hazard
20 improvements in the Nation’s critical infrastructure. Common lessons from
21 earthquakes, hurricanes, floods, severe accidents, and human threats should be
22 synthesized and general principles adopted for improving hazard-related lifeline
23 component and system performance.

24 25 **F. Disaster Response (Member #10)**

26 27 ***F.1 General***

28 NEHRP continues to be a uniting effort that provides concepts of planning, response,
29 relief, recovery, and reconstruction in an all-hazards environment. NEHRP provides the
30 backbone for learning lessons from other disasters and integrating science into
31 emergency management. There is a long and close collaborative relationship between the
32 USGS and FEMA in dealing with sudden onset events, as well as those that are
33 catastrophic.

34 35 ***F.2 Achievements***

36 Substantial new developments in disaster response, relief, recovery, and reconstruction
37 are available and continue to be documented from the lessons learned from recent
38 disasters, particularly Hurricane Katrina. Major NEHRP efforts include the regional
39 catastrophic response planning efforts in northern and southern California and in the New
40 Madrid Seismic Zone, which are driven by ground motion models developed by the
41 USGS, generating losses from HAZUS, and planning and plans supported by FEMA. The
42 scenarios based on the work of the USGS and FEMA are being paired with regional
43 catastrophic planning and exercise efforts supported by the DHS and FEMA to identify
44 response gaps and build organizational relationships between states and federal response
45 capacity. Planning for response and recovery from extreme events such as earthquakes
46 benefits many of the concepts and methodologies used to address other extreme loads.

1 The multi-hazards demonstration project in southern California and the Golden Guardian
2 earthquake response exercises undertaken in northern California and planned for southern
3 California are noteworthy activities that will undoubtedly result in improved disaster
4 response and recovery capabilities.

5
6 Additional achievements involve development and use of ShakeMap, ShakeCast, CISN
7 Display, and other products affiliated with ANSS in alert and notification and response
8 and recovery planning; the building code concepts of performance-based design and the
9 critical importance of non-structural enhancements to build resiliency and reduce damage
10 and losses, which have been influenced by seismic design. Technological developments
11 related to earthquake early warning systems and the parallel assessment of the societal
12 implications of such technology offer promise to assessment and communication of
13 threats and risks to the public.

14
15 A critical element of NEHRP is the continuous gathering of knowledge and
16 improvements to practice through the multidisciplinary Learning from Earthquakes
17 (LFE) program. LFE provides the model for continuous improvement to engineering and
18 emergency management practice that should be broadened to address the multi-hazard
19 environment.

20 21 ***F.3 Issues and Challenges***

22 Additional work is required to enable effective implementation of planning for disaster
23 response, relief, recovery, and reconstruction, including the following:

- 24
25 • Develop catastrophic and disaster planning scenarios in major urban areas prone
26 to earthquakes based on ground motion mapping from the USGS.
- 27 • Enhance the HAZUS loss estimation tools developed by FEMA to address
28 tsunami inundation (USGS, NSF, and the National Oceanic and Atmospheric
29 Administration (NOAA)); enhance the building inventory data (FEMA); update
30 fragility functions (NSF, NIST, FEMA); and fully integrate ShakeMap,
31 ShakeCast into a fully automated loss estimation tool.
- 32 • Continue to support the assessment of the technological and societal factors
33 related to earthquake early warning methodologies.
- 34 • Undertake research to better understand the vulnerability of communities,
35 particularly the impacts of disasters on fragile populations and the roles of non-
36 governmental organization (NGO) service providers and volunteers (individuals,
37 NGOs, and corporate sector) for post-disaster response, relief, and recovery.
- 38 • Continue the collaboration between USGS and NOAA in enhancing the regional
39 seismic networks and coordinate timely tsunami warning with earthquake
40 warnings in collaboration with the NOAA
- 41 • Undertake comprehensive assessments of community relief, recovery, and
42 reconstruction to inform and expedite post disaster recovery planning.
- 43 • Continue the assessment of post-disaster housing by exploring innovative
44 technologies for construction and integration of interim housing into community
45 restoration, reconstruction, and social and economic recovery.
- 46
